1 General Security Principles

1.1 Protection of User Data in Dashlane

Protection of user data in Dashlane relies on 4 separate secrets:

- The **User Master Password**:
  - It is never stored on Dashlane servers, nor are any of its derivatives (including hashes).
  - By default, it is not stored locally on disk on any of the user’s devices; we simply use it to (de)crypt the local files containing the user data.
  - It is stored locally upon user request when enabling the feature “Remember my Master Password”.
  - In addition, we ensure that the user’s Master Password is never transmitted over the internet [1].

- In some cases (local storage), we use an **Intermediate Key** (random 32-byte) encrypted with the derived Master Password.

- A unique **User Device Key** for each device enabled by a user:
  - Auto generated for each device.
  - Used for authentication.

1.2 Local Access to User Data

Access to the user’s data requires using the **User Master Password** which is only known by the user. It is used to generate the symmetric Advanced Encryption Standard (AES) 256-bit key for encryption and decryption of the user’s personal data on the user’s device.

We use Webcrypto API for most browser based cryptography and the native libraries for IOS and Android.

1.3 Local Data Usage After decrypting

Once the user has input their Master Password locally in Dashlane and their user data has been decrypted, data is loaded in memory.

The Dashlane client operates within significant constraints to use decrypted user data effectively and securely:

- Dashlane processes decrypt and access individual passwords to autofill them on websites or to save credentials without having to ask the user for the Master Password each time.

- The passwords are sent from different processes through named pipes or web sockets from core to plugins (but are encrypted using AES first).

- The Argon2d (or PBKDF2) derivation used to compute the AES keys adds significant latency (on purpose to protect against brute force attacks).

  See in paragraph **Memory Protection** for more on memory management.
1.4 Use of 2FA Applications to Increase User Data Safety

At any time, a user can link their Dashlane account to a 2FA application on their mobile device (we recommend using Dashlane Authenticator, or alternatives such as Google Authenticator). All of their data, both the data stored locally and the data sent to Dashlane servers for synchronization purposes are then encrypted with a new key, which is generated by a combination of the User Master Password and a randomly generated key called the User Secondary Key stored on Dashlane server, as described in the following steps:

- The user links their Dashlane account with their 2FA application.
- Dashlane servers generate and store a User Secondary Key, which is sent to the user's client application.
- All personal data are encrypted with a new symmetric AES 256 bits key generated client side from both the User Master Password and the User Secondary Key.
- The User Secondary Key is never stored locally.
- The next time the user tries to log into Dashlane, they will be asked by Dashlane servers to provide a One-Time Password generated by the 2FA application. Upon receiving and verifying this One-Time Password, Dashlane servers will send the User Secondary Key to the client application, allowing the user to decrypt their data.

Doing so, user data can be decrypted only by having both the User Master Password, and the 2FA application linked to the user’s account.

1.5 Authentication

As some of Dashlane’s services are cloud-based (data synchronization between multiple devices for instance) there is a need to authenticate the user on Dashlane servers.

Authentication of the user on Dashlane servers is based on the User Device Key and has no relationship with the User Master Password.

When a user creates an account or adds a new device to synchronize their data, a new User Device Key is generated by the servers. The User Device Key is composed of 40 random bytes generated using the OpenSSL RAND_byte function. The 8 first bytes are the access key and 32 remaining bytes are the secret key.

This User Device Key is received by the user’s device and is stored locally in the user data, encrypted as all other user data as explained earlier. On the servers’ side, the secret key part is encrypted so that employees cannot impersonate a given user device. When a user has gained access to their data using their Master Password, Dashlane is able to access their User Device Key to authenticate them on our servers without any user interaction.

As a result, Dashlane does not have to store the user Master Password to perform authentication.

1.6 Communication

All communications between the Dashlane application and the Dashlane servers are secured with HTTPS. HTTPS connections on the client side are performed using OpenSSL.

---

[1] Key Length: 2048-bit, Signature algorithm = SHA2 + RSA.

---

1 GENERAL SECURITY PRINCIPLES
The HTTPS communications between Dashlane application and the Dashlane servers are using SSL/TLS connections.

Main TLS protocol steps are as follow:

- The client and the server negotiate to choose the best cipher and hash algorithm available on both side.
- The server sends a digital certificate.
- The client verifies the certificate by contacting a Certificate Authority.
- The client encrypts a random number with the server’s public key and sends it to the server.
- The server decrypts this number, and both sides use this number to generate a symmetric key, used to encrypt and decrypt data.

1.7 Details on Authentication Flow

The initial registration for a user follows the flow described in Figure 1.

As seen in Figure 1, the User Master Password is never used to perform server authentication, and the only keys stored on our servers are the User Device Keys.
When adding a second device, the important point is that Dashlane needs to make sure the user adding the additional device is indeed the legitimate owner of the account. This is to gain additional protection in the event the User Master Password has been compromised and an attacker who does not have access to their already-enabled device is trying to access the account from another device.

As shown on Figure 2, when a user is attempting to connect to a Dashlane account on a device that has not yet been authorized for this account, Dashlane generates a One-Time Password (a Token) that is sent to the user either to the email address used to create the Dashlane account initially or by text message to the user’s mobile phone if the user has chosen to provide their mobile phone number.

In order to enable the new device, the user has to enter both their Master Password and the Token. Only once this two-factor authentication has been performed will Dashlane servers start synchronizing the user data on the new device. All communication is handled with HTTPS and the user data only travels in AES-256 encrypted form. Please note again that the User Master Password never transmits over the internet.
1.8 Keeping the User Experience Simple

All along, our goal is to keep the user experience simple and to hide all the complexity from the user. Security is growing more and more important for users of cloud services but they are not necessarily ready to sacrifice convenience for more security.

Even though what goes on in the background during the initial registration steps is complex (see Figure 3), the user experience is very simple. All they have to do is to pick a (strong) Master Password, and all the other keys are generated by the application without user intervention.

When adding an additional device, the process is equally simple while remaining highly secure through the use of two-factor authentication described in Figure 4.

1.9 Use of 2FA Application to Secure the Connection to a New Device

At any time, a user can link their Dashlane account to a 2FA application on their mobile device. When they attempt to connect into a new device, instead of sending...
Dashlane asks the user to provide a One-Time password generated by the 2FA application.

After receiving and verifying the One-Time Password provided by the user, Dashlane servers will store the User Device Key generated by the client application, as described in Figure 4.

### 1.10 2-Factor Authentication

Dashlane offers 2-Factor Authentication that can be activated from the security settings in the Web extension to force the usage of a second factor each time the user logs into Dashlane.

Supported two-factor methods include 2FA applications such as Google Authenticator or U2F compatible devices such as Yubikeys. U2F is an open protocol from the FIDO Alliance ([https://fidoalliance.org](https://fidoalliance.org)). Dashlane is a member of the FIDO Alliance.

### 1.11 Sharing Data Between Users

Dashlane allows users to share credentials and secure notes with other users, or with groups of users, in such a way that Dashlane never directly accesses a user’s data at any point. In fact, Dashlane’s servers never have access to the content of shared data.

Dashlane’s sharing relies on asymmetric encryption; upon account creation, a unique pair of public and private RSA keys are created by the Dashlane application for each user. The private key is stored in the user’s personal data, and the public key is sent to Dashlane’s servers. RSA public and private keys are generated using the OpenSSL function RSA_generate_key_ex, using a key length of 2048 bits, with 3 as a public exponent.

Here is the process for a user, Alice, to share a credential with another user, Bob:

- Alice asks Dashlane’s servers for Bob’s public key.
- Alice generates a 256-bit AES key, using a cryptographically secure random function on each platform. This key is unique for each shared item and is called an ObjectKey.
- Alice encrypts the ObjectKey using Bob’s public key, creating a BobEncryptedObjectKey.
- Alice sends the BobEncryptedObjectKey to Dashlane’s servers.
- Alice encrypts her credential with the ObjectKey, using AES-CBC and HMAC-SHA2 creating an EncryptedCredential.
- Alice sends the EncryptedCredential to Dashlane’s servers.
- When Bob logs in, Dashlane’s servers inform him that Alice wants to share a credential with him. Bob must manually accept the item in his Dashlane application and sign his acceptance using his private key.
- Upon acceptance, Dashlane’s servers send Bob the BobEncryptedObjectKey, and the EncryptedCredential.
- Bob decrypts the BobEncryptedObjectKey with his private key and gets the ObjectKey.
- Bob decrypts the EncryptedCredential with the ObjectKey and adds Alice’s plain text credential to his own personal data.
Sharing data with a group of users follows the same security principle: Use a user’s RSA public and private keys to send protected AES keys, sign a user’s action, and use intermediary AES keys to exchange data.

To summarize:

- Each user has a pair of public and private RSA 2048-bit keys:
  - Public keys are used to encrypt information only a specific user can decrypt.
  - Private keys are used to sign actions users are performing.
- For each credential or secure note shared, an intermediary AES 256-bit key is created and used to perform data encryption and decryption.

### 1.12 Account Recovery

Account Recovery allows Dashlane Business users to regain access to Dashlane by resetting their Master Password. Our patented process preserves a zero-knowledge architecture. Through Account Recovery, Master Passwords are never stored on any servers nor transmitted in any form.

Our solution allows users to reset their Master Password and recover the data stored on an authorized device. Account Recovery is an optional feature admins can activate for their Dashlane Business account in the Admin Console.

To enable recovery, the user’s local key — itself encrypted with the user’s Master Password — is also encrypted using a unique user recovery key, which is generated and used for all of the user’s devices when they opt into Account Recovery. This user recovery key is then encrypted using a unique server-side recovery key, which is only known to Dashlane and the user’s client devices. When an admin enables Account Recovery, their public key is used to encrypt the server-side recovery key which, as aforementioned, was already used to encrypt the user’s recovery key. An admin can then, via their private key, later access the user’s recovery key protected by the server-side recovery key.

When a user requests Account Recovery, they are asked to verify their account and create a new Master Password. A critical step of the recovery process is the verification of the identity of the user. It is up to the admin, acting as a trusted third-party, to ensure the user requesting recovery is indeed the owner of the account. If an admin approves the request, the server-side recovery key, which protects the user’s recovery key, is securely exchanged from the admin to the user through a public/private key system. On the user’s device, the user’s recovery key is then decrypted using the server-side recovery key, provided by Dashlane after the user’s identity and request have been validated. The user’s recovery key is then used to decrypt the user’s local key, which in turn is used to decrypt the user’s data. The recovered data is then re-encrypted with the new Master Password and re-synced to the Dashlane servers.

As this process involves a Master Password change, all of the user’s devices have to be registered once again to Dashlane for the user to access their newly encrypted data.

Important privacy note: the Account Recovery process relies on the Admin being a trusted Third-Party. In case the Dashlane Admin has access to both the user’s device and the user’s email used as a Dashlane account, he would be in a position to trigger an Account Recovery from the user’s device and get access to the user’s vault and personal data.
1.13 Single Sign On (SSO)

1.13.1 Introduction

Dashlane Business supports login with Single Sign On (SSO), using any SAML 2.0 enabled IDP.

In a single sign-on setup, the user doesn’t have to input a Dashlane Master Password. Instead, a random key is generated at account creation. This key (the data encryption key) is delivered to the Dashlane Application after the user successfully logs in to the IDP, and is used as a symmetric encryption key to encrypt and decrypt the user data.

This section details how the key is stored and delivered to the user in order to make sure that the zero knowledge principle is maintained.

1.13.2 General principle

In order to avoid storing all the keys in one place, the data encryption key is composed of 2 parts:

- 64 random bytes hold by the SSO connector.
- 64 random bytes hold by Dashlane's servers, in the cloud.

The SSO connector is a server component that the customer operates (either in the cloud or on premise). It acts as the service provider in the SAML 2.0 flow. After a successful authentication to the SSO Connector using SAML, the first part of the key is delivered to the Dashlane Client Application, along with a token that allows to get the second part from the Dashlane Server.

Once both parts of the keys are retrieved by the Client Application, they are XORed together, and the resulting 64 bytes are used as a symmetric key to encrypt and decrypt user data.

This system ensure zero-knowledge as the first part of the key is only known by the SSO Connector and the Client Application, both of which are managed by the customer.

It also makes sure that a compromised SSO Connector cannot be used to fetch the keys of users without leaving traces on Dashlane Servers (an API call to Dashlane Server is required to fetch the second part of the key).

1.13.3 Services

Dashlane Server / API (API) The servers operated by Dashlane in the cloud, where user data is stored encrypted.

SSO Connector (SP) A service acting as the service provider in the SAML 2.0 flow. The service is distributed by Dashlane, but hosted and managed by the customer on premise or in the cloud.

Identity Provider (IdP) The SAML 2.0 identity provider (e.g. ADFS, Azure AD, Okta) of the customer. This service is not provided by Dashlane. It is operated by the customer or by a third party.
1.13.4 Keys, secrets and certificates

IdP key and certificate (IdP_Key / IdP_Cert) Public and private keys of the IdP. The private key is hold by the IdP, while the certificate needs to be provided to the SP in the configuration file. It is used by the IdP to sign and by the SP to verify the SAML assertions.

Master SP Key / SSO Connector Key (master_sp_key) A 64 bytes secret key, generated randomly by the Team Admin Console (client side). It is stored in the configuration file of the SP, and is only known by the Team Admin. It is used by the SP to encrypt/decrypt the user_sp_key before storing them in the API.

User SP Key (user_sp_key) A 64 bytes secret key, generated randomly by the SP. It is stored encrypted in the API.

User Server Key (server_key) A 64 bytes secret key, generated randomly by the client. It is stored unencrypted in the API.

User vault key (vault_key) user_sp_key XOR server_key. It is used by the client to encrypt/decrypt user’s data before storing them in the API.
1.13.5 Workflow

![Diagram showing the SSO Workflow]

Figure 5: SSO Workflow
2 Impact on Potential Attack Scenarios

Today, cloud-based services make various choices to encrypt their user data. These choices have important consequences in terms of security.

2.1 Minimal Security Architecture

Cloud services can use a single private secret, usually under their control, to encrypt all user data. This is obviously a simpler choice from an implementation standpoint, plus it offers the advantage of facilitating deduplication of data which can provide important economic benefits when the user data volume is important. Obviously, this is not an optimal scenario from a security standpoint since if the key is compromised (hacker attack or rogue employee), all user data is exposed.

![Figure 6: Potential Attack Scenarios With Minimal Security](image)

2.2 Most Common Security Architecture

A better alternative is to use a different key for each user. The most common practice is to ask the user to provide a (strong) Master Password and to derive the encryption key for each user from their Master Password. However, to keep things simple for the user, many services or applications tend to also use the user’s Master Password as an authentication key for the connection to their services. This implies that an attacker could access a user’s vault by just knowing the master password. It could also easily lead to implementation errors (missing salt/rainbow tables attacks, wrong/weak hashing, etc.).
2.3 Dashlane Security Architecture

In order to make this attack scenario impossible, we have made the decision to separate the key used for user data encryption and the key used for server based authentication (see Figure 8). The user data is encrypted with a key which is a derivative of the User Master Password. A separate User Device Key (unique to each device-user couple) is used to perform authentication on Dashlane Servers. This User Device Key is automatically generated by Dashlane. As a result:

- Encryption keys for user data are not stored anywhere.
- No Dashlane employee can ever access user data.
- User data is protected by the Master Password even if Dashlane's servers are compromised.
Even if this scenario happens, a rogue employee or an external hacker would have a very hard time executing a brute force or dictionary attack on the AES user data files, as we use the Argon2d (or PBKDF2-SHA2) algorithm. As the user data are encrypted using a salted key which is a derivative of their User Master Password, no rainbow attacks are possible.

### 2.4 Anti-Clickjacking Provisions

In order to protect Dashlane users from rogue websites that would attempt to use clickjacking tactics or other JavaScript based attacks to extract data from the Dashlane application, we have made sure none of the webpage-based interactions involving user data unrelated to this website use JavaScript.

The popups used to trigger form-filling on a webpage uses various browser security APIs to prevent control from the JavaScript of the visited page. As a result, a rogue website cannot trigger a click that would cause Dashlane to believe that the user has actually clicked, and therefore, cannot extract information unless the user explicitly clicks in the field.

### 2.5 Same-origin Policy

Dashlane automatically logs users into websites. In order to avoid providing user’s information to rogue websites, the same-origin policy is always respected.

First, a credential saved by Dashlane when it has been used on a website with the URL of mysubdomain.mydomain.com will not be automatically filled on another website with the URL of myothersubdomain.mydomain.com. This prevents the credential of a specific website from being provided to another website which would share the same top-level domain name.

Also, a credential saved by Dashlane when it has been used on a website with a
2.6 Memory Protection

A problem can arise if an attacker takes control of the user’s client device. In that scenario, the attacker could retrieve the decrypted user data from the memory.

This is an extreme scenario as, in that case, the attacker can take control of many parts, including adding a keylogger to capture the Master Password.

- Mobile operating systems (Android, IOS) ensure that no process can ever access the memory of another process and are not directly affected.

Finally, we believe the system integrity and security between processes is a system function and Dashlane cannot (and should not) reinvent the wheel and add useless complexity that could lead to other vulnerabilities and have negative side-effects on antivirus.
